ABSTRACT

Endocrine disrupting chemicals (EDCs) are emerging contaminants that can interfere with the hormone system and may cause cancers, birth defects and reproductive system disorders. Prevalence of endocrine-related dysfunction and disease has increased steadily over the past decades. Although accumulating data suggest that these diseases have fetal origins, associations of EDC exposure during pregnancy and adverse health effects on both mothers and fetuses have not been thoroughly evaluated, particularly at multiple points in time.

We firstly developed an analytical method for quantification of 28 EDCs (9 phthalates, 8 bisphenols, 5 parabens, 5 benzophenones and triclosan) in urine samples using ultra high performance liquid chromatography coupled with triple quadrupole mass spectrometer. The method was applied to measure targeted compounds in a total of 5220 urine samples collected from 951 pregnant women at three trimesters and 1501 pregnant women at one or two trimesters in Wuhan, China between 2014 and 2015. Based on the quantification results, exposure patterns and health risks of 28 EDCs on participants were evaluated and discussed in detail below.

Among these samples, bisphenol A (BPA), bisphenol S (BPS), bisphenol F (BPF), methylparaben (MeP), ethylparaben (EtP), propylparaben (PrP), 4-hydroxybenzophenone (4-OH-BP), 2,4-dihydroxybenzophenone (BP-1), 2-hydroxy-4-methoxybenzophenone (BP-3), triclosan, mono(2-ethylhexyl) phthalate (MEHP), mono(2-ethyl-5-carboxypentyl) phthalate (MECPP), mono(2-ethyl-5-oxohexyl) phthalate (MEOHP), mono(2-ethylhexyl) phthalate (MEHHP), monobenzyl phthalate (MBzP), mono-n-butyl phthalate (MnBP), monoisobutyl phthalate (MiBP) were determined with detection rates exceeding

50%, in which BPA, BP-3, MeP and MnBP were the predominant compounds. We found the U-shaped trends of urinary concentrations of phthalate metabolites over trimesters. Parabens, benzophenones and triclosan displayed a downward trend over three visits. We also found the levels of targeted compounds varied by exposure-related factors, such as sampling seasons, physical activities, computer using time and decoration information. In addition, multiple EDCs were mostly determined at low doses over trimesters, indicating that real-world exposure of pollutants were dominated by low-dose mixtures.

We then evaluated the combined health hazards induced by EDC exposure via calculating the estimated daily intakes on the basis of average urinary concentrations at three trimesters. It was found that 24.9% of participants had potential health risks caused by exposure to phthalate mixtures. The most frequency of cumulative risks occurred in women who were exposed to a high dose of one specific phthalate, di-n-butyl phthalate (DnBP) or di(2-ethylhexyl) phthalate (DEHP). We also evaluated the cumulative health risks of BPA and its alternatives and found that about 1.6% of participants were at risks induced by bisphenol exposure. Combined health hazards were mainly driven by one specific bisphenol (BPS or BPA). Our findings suggested that regional interventions of DnBP, DEHP, BPA and BPS in application and production should be tighten and/or taken.

Considering the low-dose effects of BPA, we further investigated the associations of BPA and three major natural estrogens, including estrone (E1), estradiol (E2) and estriol (E3), at three trimesters of pregnancy. We observed non-monotonic dose-response relationships of BPA to E1, E2 and E3 over trimesters even when BPA concentrations were below the current safety

thresholds. In the gender-stratified models, we found significant negative relationships ($\beta < 0$, $p < 0.05$) between BPA and E2 among mothers with male fetuses in the first trimester. However, we found that no significant relationship between BPA and E2 among mothers with female fetuses over three trimesters. Significant non-monotonic associations (from significant negative to positive associations) between BPA and E3 were observed among mothers with female fetuses in the second trimester. The above mentioned findings suggested the gender-specific and trimester-specific effects of BPA on estrogens. Our findings also indicated that the current tolerance daily intake value maybe not safe enough to evaluate the potential health risks induced by BPA exposure.

We next investigated the effects of maternal exposure to phthalates on both mothers and fetuses. Associations of phthalate exposure with the risks of gestational diabetes mellitus (GDM) and plasma glucose levels were evaluated based on a nested case-control study design. It was found that the levels of phthalate metabolites in women with GDM were significantly higher than those without GDM. Meanwhile, positive associations between urinary concentrations of phthalate metabolites and the risks of GDM were obvious, indicating that phthalate exposure may be a risk factor for GDM. In addition, phthalate levels were related to the increased plasma glucose levels after 75 g oral glucose tolerance test. Our findings suggested that phthalates might disturb the glucose homeostasis and increase GDM risks.

Furthermore, we assessed the trimester-specific and gender-specific effects of DEHP exposure on fetal growth, birth size and postnatal growth at 6, 12 and 24 months. We found that among male offspring, 1st-trimester DEHP was negatively related to fetal growth ($\beta < 0$, $p < 0.05$), but positively related to 24-month body

mass index (BMI). 2nd-trimester DEHP was negatively related to fetal growth, birth weight and birth length, but positively related to the weight gain rates from birth to 12 months old. 3rd-trimester DEHP was positively ($\beta > 0$, $p < 0.05$) associated with birth weight, BMI at 6 and 12 months. However, among females, 1st-trimester DEHP was associated with increased birth length, while 2nd-trimester DEHP was negatively associated with BMI at 6 and 12 months. A negative association between DEHP and weight gain rates at 6 months was noted among females. Our findings indicated the second trimester maybe the sensitive window of DEHP exposure for offspring growth since 2nd-trimester DEHP levels were related to the decreased fetal growth, decreased birth size, but increased weight gain rates in early childhood age among male offspring.

To investigate the mechanism underlying the associations of DEHP exposure with glucose and lipid metabolism, we investigated the biotransformation of DEHP and the disturbed metabolisms induced by MEHP, the putative toxic metabolite of DEHP, in human normal liver cell L02 using metabolomics and lipidomics. We found that MEHP was the major metabolite of DEHP. Decreased uptake of glucose and accumulation of glucose in liver cells were obvious after MEHP exposure. Phospholipid remodeling, incomplete fatty acid β -oxidation, inhibition of purine metabolism and glycolysis, and increased oxidative stress were noted in MEHP-exposed L02 cells, which were related to insulin resistance.

In this work, we measured 28 EDCs in a total of 5220 urine samples provided by 951 pregnant women (three trimesters) and 1501 pregnant women (one or two trimesters) and then evaluated the exposure levels, exposure patterns (variations, variability and correlations), health risks and health effects of these compounds on pregnant women and fetuses. Our data suggested that participants had potential

health risks induced by exposure to phthalates or bisphenols. Phthalate exposure was related with the increased plasma glucose levels and risks of GDM. Prenatal DEHP exposure may induce the intrauterine growth restriction and catch-up growth among males, which supported the evidence of fetal origin. To explore the underlying mechanisms of MEHP on glucose and lipid metabolic disorders, we exposed the human normal hepatic L02 cells with MEHP, and applied metabolomic and lipidomic approaches for finding potential biomarkers and disturbed pathways. We found that MEHP exposure inhibited glucose uptake, caused phospholipid remodeling and increased oxidative stress in L02. These findings suggest that the usage of products containing EDCs, particularly phthalates, in pregnant women should be limited in China, intervention of BPS should be considered, and threshold values of BPA are called for reevaluation.

DECLARATION	i
ABSTRACT	ii
ACKNOWLEDGEMENTS	vii
Table of Contents	viii
List of Tables	xvi
List of Figures	xx
List of Abbreviations	xxiv
Chapter 1 General introduction	1
1.1 Endocrine disrupting chemicals.....	1
1.1.1 Phthalates	3
1.1.2 Bisphenols.....	6
1.1.3 Parabens.....	7
1.1.4 Benzophenones	7
1.1.5 Triclosan	8
1.2 Determination of EDCs in urine samples from pregnant women	8
1.3 Exposure profiles of EDCs among pregnant women.....	10
1.4 International convention and health risk assessment	11
1.5 Adverse health effects of EDC exposure during pregnancy	13
1.5.1 Dose-dependent associations between BPA and natural estrogens	15
1.5.2 Gestational diabetes mellitus	15
1.5.3 Adverse birth outcomes	16
1.6 Metabolomics and lipidomics.....	17
1.6.1 High-resolution mass spectrometry-based metabolomics	19

1.6.2 Lipidomics	20
1.7 Aims of the project.....	20
Chapter 2 Determination of typical endocrine disrupting chemicals including phthalates, bisphenols, parabens, benzophenones and triclosan in urine samples.....	22
2.1 Introduction	22
2.2 Experimental section.....	25
2.2.1 Chemicals and reagents	25
2.2.2 Standard preparation and calibration.....	26
2.2.3 Method validation	26
2.2.4 Sample preparation by liquid-liquid extraction	27
2.2.5 Ultra-performance liquid chromatography condition	30
2.2.6 Mass spectrometry condition	30
2.2.7 Quality control	31
2.3 Results and discussion	31
2.3.1 Development and validation of LC-MS condition.....	31
2.3.2 Method validation	36
2.4 Chapter summary.....	43
Chapter 3 Exposure assessment of phthalates, bisphenols, parabens, benzophenones and triclosan during pregnancy	44
3.1 Introduction	44
3.2 Materials and Methods.....	47
3.2.1 Study population and sample collection.....	47
3.2.2 Covariates	47
3.2.3 Gestational age.....	49

3.2.4 Urinary concentrations of EDCs	49
3.2.5 Daily intake dose.....	52
3.2.6 Cumulative risk assessment	53
3.2.7 Statistical analysis	54
3.3 Results and discussion	56
3.3.1 General characteristics of participants	56
3.3.2 Exposure assessment of phthalates	59
3.3.2.1 Exposure levels of phthalate metabolites.....	59
3.3.2.2 Evaluation of exposure levels at three visits	65
3.3.2.3 Within-person variability and correlations of biomarkers between study visits	69
3.3.2.4 Exposure to percentiles of phthalates	71
3.3.2.5 Health risk assessments of phthalates.....	74
3.3.2.6 Demographic factors associated with phthalate levels and indicators	79
3.3.2.7 Demographic factors associated with HI and MCR	88
3.3.3 Exposure assessment of bisphenols.....	91
3.3.3.1 Exposure profiles of bisphenols	91
3.3.3.2 Correlations of bisphenols	98
3.3.3.3 Exposure to an individual or three bisphenols at single or three trimesters.....	99
3.3.3.4 Variability of bisphenols	100
3.3.3.5 Demographic factors associated with urinary bisphenol levels.....	101
3.3.3.6 Average urinary concentrations of bisphenols over three	

trimesters	104
3.3.3.7 Health risk assessments of bisphenols	105
3.3.3.8 Groups according to the values of HI and MCR	107
3.3.3.9 Relationships between HI and MCR	109
3.3.3.10 Contributions of a single bisphenol in 25 th , 50 th , 75 th , 95 th percentiles of HI.....	111
3.3.3.11 Associations of demographic factors with HI and MCR	113
3.3.4 Exposure assessments of parabens, benzophenones and triclosan	115
3.3.4.1 Maternal urinary concentrations of parabens, benzophenones and triclosan	115
3.3.4.2 Variability and correlations of parabens, benzophenones and triclosan	121
3.3.4.3 Associations of urinary concentrations of parabens, benzophenones and triclosan with the possible determinants	123
3.3.4.4 Co-exposure and source analysis.....	129
3.4 Chapter summary.....	132
Chapter 4 Bisphenol A in relation to three natural estrogens: estrone, 17β-estradiol and estriol in a repeated-measures study	133
4.1 Introduction	133
4.2 Materials and methods	134
4.2.1 Study population	134
4.2.2 Measurement of maternal urinary concentrations of BPA and estrogens.....	134
4.2.3 Estimated daily intake of BPA	135

4.2.4 Statistical analysis	135
4.3 Results	136
4.3.1 Characteristics of the study population	136
4.3.2 Urinary concentrations of BPA, E1, E2 and E3	138
4.3.3 Associations between BPA and three estrogens	141
4.3.4 Gender-specific associations between BPA and estrogens	152
4.4 Discussion	157
4.5 Chapter summary	162
Chapter 5 Maternal exposure to phthalates in relation to both gestational diabetes mellitus and glucose homeostasis: A nested case-control study	163
5.1 Introduction	163
5.2 Materials and methods	164
5.2.1 Study design and study population.....	164
5.2.2 Gestational diabetes mellitus diagnosis and plasma glucose measurements	164
5.2.3 Samples collection and measurement of urinary concentrations of phthalates.....	165
5.2.4 Statistical analysis	165
5.3 Results	166
5.3.1 Characteristics of participants included in the case-control study of GDM	166
5.3.2 Levels of biomarkers among GDM and non-GDM	169
5.3.3 Associations between biomarkers and risks of GDM	173
5.3.4 Gender-dependent effects of biomarkers on GDM risks.....	177
5.3.5 Associations between biomarkers and plasma glucose homeostasis	

.....	180
5.4 Discussion	183
5.5 Chapter summary.....	189
Chapter 6 Effects of prenatal exposure to di(2-ethylhexyl) phthalate (DEHP) on fetal growth, birth size, and early-childhood growth: A longitudinal prospective cohort study	190
6.1 Introduction	190
6.2 Methods.....	191
6.2.1 Fetal and early-childhood growth measurements	191
6.2.2 Statistical analysis	192
6.3 Results.....	194
6.3.1 Study population	194
6.3.2 Maternal urinary concentrations of phthalate metabolites	198
6.3.3 Trimester-specific associations of prenatal DEHP exposure levels and fetal growth.....	201
6.3.4 Trimester-specific associations of prenatal DEHP exposure levels with birth size and postnatal growth.....	207
6.3.5 Trimester-specific associations of prenatal exposure levels of DEHP and its metabolites with average early-childhood growth.....	211
6.3.6 Associations of average prenatal exposure levels of DEHP and its metabolites with fetal growth and birth size	215
6.3.7 Associations of average prenatal exposure levels of DEHP and its metabolites with early-childhood growth.....	218
6.3.8 Effects of DEHP and its metabolites on early-childhood growth rates	224

6.4 Discussion	228
6.5 Chapter summary	232
Chapter 7 Metabolomics and lipidomics study of MEHP exposure on human liver cells	233
7.1 Introduction	233
7.2 Materials and methods	234
7.2.1 Chemicals and materials	234
7.2.2 Cell culture and cytotoxicity of MEHP and DEHP on L02 cells	235
7.2.3 DEHP biotransformation products	236
7.2.4 Metabolomics	236
7.2.5 Lipidomics	237
7.2.6 Data analysis	238
7.3 Results and discussion	240
7.3.1 Cytotoxicity assay after incubation with DEHP and MEHP	240
7.3.2 Glucose intakes after incubation with DEHP and MEHP	241
7.3.3 Biotransformation of DEHP	242
7.3.4 Potential biomarkers and perturbed metabolic pathway	246
7.3.5 Identification of significantly changed metabolites	249
7.3.6 Pathway analysis	254
7.3.7 Lipids and perturbed lipid metabolism	257
7.3.8 Analysis of MEHP exposure disturbed pathways	261
7.4 Chapter summary	266
Chapter 8 Conclusions and future work	267
