ABSTRACT

Introduction – *Dioscorea nipponica* (DN) and *D. panthaica* (DP) have been uniquely prepared as herbal medicinal products for treating coronary heart disease (CHD) in China. However, so far there has been little discussion and no work comparing the qualitative and quantitative differences between the two herbs nor assessing whether they have similarities in chemical composition that would support their common application for treating CHD.

Objective – To develop an efficient and reliable method based on UPLC-qTOF-MS for quantitative comparison of saponins in both DN and DP.

Methodology – Using electrospray ionization and atmospheric-pressure chemical ionization respectively, six steroidal glycosides and one aglycone were determined in 13 DN samples and 13 DP samples. The comparative analysis of chemical components in DN and DP was carried out by chromatographic fingerprint similarity evaluation, test of significance (*t*-test) and principle component analysis (PCA).

Results – The UPLC-qTOF-MS method showed limit of detection and quantitation within the range 0.02-0.2 ng and 0.08-0.5 ng, respectively, for the 7 studied saponins. The intra- and inter-day precision (RSD) was below 5%. The recoveries for the quantified compounds were within the range of 72.79-118.31%.

Conclusion – This UPLC-qTOF-MS assay provides a suitable method for the identification and determination of major bioactive constituents both in DN and DP. The chemical composition of all DN and DP samples studied exhibited a high level of global similarity. This chemical similarity validates their common application in the pharmaceutical industry as anti-CHD herbal drugs.

Dioscorea nipponica, *Dioscorea panthaica*, steroidal saponins, principal component analysis, chromatographic fingerprint similarity, UPLC-qTOF-MS

Introduction

Plants of the *Dioscorea* genus (family Dioscoreaceae) with significant edible or medicinal values have long been the research focus of both the food and pharmaceutical industries. Known as yam, the roots and tubers of several edible species of *Dioscorea*, such as *D. opposita*, *D. alata*, and *D. japonica*, are consumed as a staple food by the populations of Africa, Asia and tropical America (Adedayo *et al.*, 2011). Medicinal species of *Dioscorea* have a wide spectrum of biological activities, for instance, anti-inflammatory, hormone-like, antitumor, immunoregulatory, hypoglycemic, and cardiovascular properties. As such, they have received a great deal of attention for the past several decades (Sautour *et al.*, 2007). In the modern pharmaceutical industry, it is well known that a few species of *Dioscorea*, such as *D. zingiberensis*, *D. nipponica* (DN), *D. panthaica* (DP) (Editorial Board of Flora of China, 1985), are important sources of diosgenin, which is used as the precursor of synthetic steroidal anti-inflammatory and hormone-based drugs. In addition, investigations into the cardiovascular activity of components of *Dioscorea* species have led to the successful development of effective pharmaceutical preparations that have been used for decades for treating cardiovascular diseases. As early as in 1975, the preparation named 'polysponin' obtained from DN was approved by the Soviet Union's Ministry of Health to be used as an anti-atherosclerosis agent and cholesterol-lowering drug in clinical practice (Leskov *et al.*, 1976; Solomonova, 1968). In China, several patented medicines indicated for myocardial ischemia or angina pectoris, such as Dioscornin Tablet (Sichuan Biology Research Institute, 1977) and Di'ao Xinxuekang Capsule (Chinese Pharmacopeia Committee, 2010), were developed during the 1970s and 1980s, and have been on the market since then; the bioactive components of these medicines are the total saponins extracted from DN or DP.

However, as far as we know, among the 49 species of the genus *Dioscorea* distributed in China (Editorial Board of Flora of China, 1985), only two have been recorded as crude drugs in the Chinese Pharmacopoeia and particularly prepared as

1
2
3 medications for treating CHD (Chinese Pharmacopeia Committee, 2010). These are
4 DN and DP, the rhizomes of which are named Chuanshanlong and Huangshanyao,
5 respectively, in folk medicine. It is also noteworthy that DN and DP are equally used
6 as starting material for Di'ao Xinxuekang Capsule, as documented in the Chinese
7 Pharmacopoeia. Interestingly, the capsule was the first Chinese patented medicine
8 authorized as a traditional Herbal Medicinal Product (tHMP) by the Dutch Medicine
9 Evaluation Board in March, 2012 (Dutch Medicines Evaluation Board, 2012). Some
10 individual research, mainly focusing on discovery of bioactive constituents contained
11 in DN or DP, has been done (Dong *et al.* 2001, 2004; Kang *et al.* 2005) with the result
12 that, up to now, a single or simultaneously two to four bioactive markers have been
13 found in quantitative assays of DN or DP using HPLC-UV (Qin *et al.* 2007) and
14 HPLC-ELSD (Liu *et al.* 2008; Shen *et al.* 2011) methods. However, the UV detection
15 wavelength for steroidal saponins is susceptible to interference from the cut-off
16 absorption wavelength of solvents in the mobile phase, such as methanol and
17 acetonitrile, and this could affect the results of quantitative analysis. Although ELSD
18 can avoid the interference caused by the wavelength of end absorption, its lower
19 sensitivity means it might be unable to quantify trace saponins. Thus, attempts to
20 establish a more sensitive and accurate method for simultaneous quantification of
21 multiple saponins in DN or DP have met with little success. Equally important, there
22 have been no attempts to make detailed comparisons of the qualitative and
23 quantitative differences between the two herbs nor to determine whether they have
24 similarities in chemical composition that support their common application in
25 anti-CHD drugs. In recent years, chemometrics coupled with liquid chromatography
26 and high resolution mass spectrum fingerprinting has become one of the most
27 frequently applied approaches in evaluation of chemical profiles of different
28 phytomedicines (Yi *et al.* 2009; Avula *et al.* 2011). This is a promising approach to
29 clarifying this unsolved problem. Compared to conventional HPLC-UV and
30 HPLC-ELSD, ultra high performance liquid chromatography coupled with
31 quadrupole time-of-flight mass spectrometry (UPLC-qTOF-MS) with its superior
32 performances in sensitivity and selectivity has been utilized in research on some

3 *Dioscorea* species, such as *D. zingiberensis*. These studies, however, focused on
4 structural elucidation and qualitative identification of steroidal saponins and provided
5 little quantitative information that could be used in comparison of detected
6 components in different herbs (Li *et al.* 2006; Zhu *et al.* 2010).
7
8

9
10
11 This paper aimed to develop a reliable and effective protocol for the quantification
12 of the major constituents, including six glycosides and one aglycone, contained in DN
13 and DP. The protocol entailed UPLC-qTOF-MS followed by comparisons of
14 chromatographic fingerprint profiles and evaluation of the contents of determined
15 components using fingerprint similarity evaluation, test of significance and principal
16 component analysis. In the present study, the chemical similarity between DN and DP
17 is evaluated and clarified so as to support their rational use in pharmacology and lay
18 the foundation for future research on the mechanism(s) of their effects on
19 cardiovascular activities.

2
3 USA) were used for the acid hydrolysis and partition of samples. Water purified using
4 a Milli-Q water system (Millipore; Bedford, MA, USA) and acetonitrile (Fisher
5 Scientific, New Jersey, USA) were used as the mobile phase for analysis. Formic acid
6 (Sigma-Aldrich, USA) was added to the mobile phase for determination of
7 glycosides.
8
9

10
11
12 Seven reference standards were used for qualitative and quantitative analysis,
13 namely six glycosides and one aglycone of diosgenin (Figure 1). The authentic
14 standards (purity > 98%) of protodioscin, dioscin, gracillin and diosgenin were
15 purchased from Phytomarker Ltd., Tianjin. Protogracillin and polyphyllin V (purity >
16 98%) used in this study were purchased from Emilion Technology Ltd., Beijing.
17 Pseudoprotodioscin was provided by National Institute for Food and Drug Control
18 (Beijing, China).

30 **UPLC-qTOF-MS analysis**

31
32
33 Ultra high performance liquid chromatography with ultra-high definition accurate
34 mass quadrupole time-of-flight mass spectrometry (Agilent Technologies, G6540A)
35 was used for qualitative and quantitative analyses. Chromatographic separation was
36 conducted on a Waters ACQUITY™ UPLC BEH C₁₈ column (1.7 μm, 2.1 × 100
37 mm). The MS spectra were acquired in negative ion mode for detecting glycosides
38 and positive ion mode for detecting aglycones. High-purity nitrogen was used as
39 nebulizer and auxiliary gas.
40
41
42
43
44
45

46 For the determination of glycosides, separation was carried out in a linear gradient
47 program, in which the mobile phase consisted of 0.1% (v/v) formic acid in water (A)
48 and 0.1% (v/v) formic acid in acetonitrile (B). The mobile phase was programmed as
49 follows: 0-2 min, 20-20% B; 2-12min, 20-28% B; 12-20 min, 28-45% B; 20-35min,
50 45-48% B. The flow rate was 0.4 mL/min. The Injection volume was 1 μL and the
51 column temperature was set at 25°C. The mass scan was over the range of *m/z*
52 50-1700 for negative ion mode with electrospray ionization (ESI) interface. The ESI

capillary voltage was set at -3.5kV for negative mode.

For the determination of aglycones, water (A) and methanol (B) were used as the mobile phases. A linear gradient program was developed as follows: 0-10 min, 55-95% B; 10-18 min, 95-95% B. The flow rate was 0.45 mL/min. The injected volume was 1 μ L and the column temperature was set at 50°C. The mass scan was over the range of m/z 100-1000 for positive ion mode with an atmospheric-pressure chemical ionization (APCI) source. The capillary voltage was set at +4.5kV. All the results were analyzed by Agilent MassHunter Workstation Qualitative Analysis B.04.00 and Quantitative Analysis (Q-TOF) B.04.00.

Sample preparation

Plant materials were cut into small pieces and mixed thoroughly. A representative portion of each of the samples was ground into a powder that passed through a 250 mesh (55 μ m) sieve. For the preparation of test solutions used to determinate steroidal glycosides, an accurately weighed portion of 0.5 g was ultrasonicated with 15 mL methanol at room temperature for 30 min. This step was then repeated twice for complete extraction. The residue was washed by an additional 5 mL of methanol. The total extracts were combined in a 50 mL volumetric flask and the volume was made up to the calibration mark with methanol. The extracts were then filtered through a syringe filter (0.2 μ m). An aliquot of 1 μ L solution was injected for UPLC-MS analysis. Three replicates were prepared for each sample.

For preparation of sample solutions used to determinate steroidal aglycones, the assay was primarily based on the procedures described in the monograph Nippon Yam Rhizome of Chinese Pharmacopeia (Chinese Pharmacopeia Committee, 2005) with minor modification. The sample solution of 25 mL for glycoside assay was transferred into a round-bottomed flask and evaporated to dryness by rotary evaporation under vacuum at 60°C. 20 mL hydrochloric acid solution (3 mol/L) was added to the residue, heated to hydrolyze on a water bath for 30 minutes, cooled, and washed with 10 mL of chloroform each time for three times. After the combined mixture was extracted

1
2
3 and partitioned, the lower layer (chloroform layer) was collected and the upper layer
4 was extracted with an additional 30 mL of chloroform once. The combined
5 chloroform layer was evaporated to dryness and the residue was dissolved by an
6 appropriate amount of methanol, transferred to a 25 mL volumetric flask and the
7 volume was made up to the calibration mark with methanol. The extracts were then
8 filtered through a syringe filter (0.2 μm). An aliquot of 1 μL solution was injected for
9 UPLC-MS analysis.

18

19 **Preparation of reference standard solutions**

20
21 Stock solutions of reference standards containing either one aglycone (diosgenin) or
22 six mixed glycosides, namely protodioscin, protogracillin, pseudoprotodioscin,
23 dioscin, gracillin, and polyphyllin V, was prepared separately. The stock solutions of
24 standards (0.5 mg/mL) were prepared in methanol and stored in the refrigerator. The
25 working solutions were prepared by appropriate dilution of the stock solutions with
26 methanol to yield seven concentrations, from 0.5 mg/L to 40 mg/L.
27
28
29
30
31
32
33
34
35

36 **Assay validation**

37
38 Linearity, precision and recovery were all carried out to validate the method,
39 according to the International Conference on Harmonization (ICH) Guidelines (ICH,
40 2005). Prepared reference standard solutions with different concentrations were
41 analyzed, and then the calibration curves were constructed by plotting the peak areas
42 versus the concentrations of each analyte. Linearity was evaluated by squared linear
43 correlation coefficient (R^2) of the calibration curves of each reference standard (Table
44 S1 in the online supporting material). Precision and recovery studies were performed
45 on the previously quantified sample of DP-02 with a representative chromatographic
46 profile, and the relative standard deviation (RSD) was taken as a measure of
47 repeatability and precision. Instrument precision was determined by analyzing known
48 concentrations of the seven analytes in the sample solution of DP-02 by consecutive
49

59
60

1
2
3 injection seven times in a single day (Table S2 in the online supporting material). To
4 confirm repeatability, triplicate samples prepared from DP-02 were analyzed once
5 daily for intra-day RSD and on three successive days for inter-day RSD (Table S2).
6
7 For the recovery test (Table S3 in the online supporting material), three spike levels
8 were set as 50%, 100% and 200% of each reference standards in DP-02. The
9 standards were spiked into 0.5 g of plant material as appropriate concentrations of
10 standard solutions. The samples were then extracted and analyzed with the described
11 method. The average percentage recoveries were evaluated by calculating the ratio of
12 detected amount versus the added amount.

25 **Results and Discussion**

26 **Optimization of extraction conditions**

27
28 Various extraction methods (e.g reflux, sonication), solvents (e.g. different
29 concentrations of methanol or ethanol), and times of extraction were evaluated to
30 obtain optimized extraction efficiency. The results demonstrated that there was no
31 significant difference in the yield of analytes between sonication and reflux, and
32 exhaustive extraction was achieved by sonication with methanol three times for 30
33 min each time.

42
43

44 **Optimization of UPLC-MS condition for detecting glycosides and aglycones**

45
46 The analytical condition was optimized mainly based on peak resolution, baseline,
47 and elution time. The mobile phase (methanol-water and acetonitrile-water) and
48 column temperature (25 °C, 40 °C or 50 °C) and column mode (BEH C₁₈ and HSS C₁₈),
49 ion source (ESI and APCI) and ion mode (negative and positive) were examined and
50 compared. Acetonitrile was preferred over methanol as the mobile phase because its
51 use resulted in an improved separation and a significantly reduced column pressure.
52 The column temperature was optimized at 25 °C for detecting glycosides and 50 °C for
53
54
55
56
57
58
59
60

1
2
3 detecting aglycones. The column BEH C₁₈ was preferred to HSS C₁₈ as the former
4 gave better peak resolution. For the selection of ion source, as it was observed that the
5 few aglycones were transformed to ion fragments under the ESI source in our pre-test.
6 Thus APCI, which provided higher fragmentor voltage, was selected for detecting
7 aglycones. Both negative and positive ion mode were tried under the ESI and APCI
8 conditions. Comparing the peak purity and number of characteristic peaks acquired
9 under different ion modes, the negative mode was chosen for testing glycosides while
10 the positive mode was chosen for testing aglycones.
11
12
13
14
15
16
17
18
19
20

21 **Assay validation**

22
23
24 The calibration curve of each analyte showed good linearity with $R^2 > 0.99$ in a wide
25 range of concentrations. The relative standard deviation (RSD) values for precision
26 were in the range of 0.54-4.96% for intra-day assays and 1.33-3.73% for inter-day
27 assays, while the RSD value for instrument precision was within 3% (Table S2). These
28 values showed that the system was suitable for the chemical analysis of the two herbs.
29 The average recovery at three spiked levels was calculated for the evaluation of
30 method accuracy. The recovery of the method was in the range of 74.14-118.31%,
31 with RSD < 6% as shown in Table S3.
32
33
34
35
36
37
38

39 Limit of detection (LOD) and limit of quantification (LOQ) were defined as a
40 signal-to-noise ratio (SNR) equal to 3 and 10, respectively. Based on stepwise dilution
41 of standard solutions and calculation of the corresponding SNR, LOD and LOQ were
42 determined within the range 0.02- 0.2ng and 0.08-0.5ng, respectively.

characteristic peaks of glycosides were identified in both DN and DP sample solutions as protodioscin (1), protogracillin (2), pseudoprotodioscin (3), dioscin (5), gracillin (6) and polyphyllin V (7) (Figure 2), and one peak of aglycone was identified as diosgenin (10) in both hydrolyzed DN and DP sample solutions (Figure 3). Base peak chromatograms (BPC) of all unhydrolyzed samples of DN and DP are shown in Figure 4 and Figure 5, respectively.

Insert Table 2 here

Insert Figure 2, Figure 3, Figure 4 and Figure 5 here

In addition, as trillin was previously discovered in DN (Wang *et al.*, 2012) and other aglycones, such as ruscogenin, tigogenin and sarsasapogenin, were found in other plants rich in saponin (Kostova and Dinchev, 2005), four additional reference standards were used to identify whether these constituents were found in the samples of DN and DP collected in our study. As seen from Figure 2 and Figure 3, no corresponding peaks of trillin (peak 8), ruscogenin (peak 9), tigogenin and sarsasapogenin (peak 11) were observed in all samples of DN and DP. Thus, diosgenin was found to be the sole aglycone in DN and DP. It was noted that as tigogenin and sarsasapogenin were diastereoisomers, as they had the same retention time and overlapped at peak 11.

Qualitative identification of two unknown compounds

The fragments of steroidal saponins revealed the characteristic cleavage of glycosidic bonds, and the fragmentation pattern provided detailed structural information about the sequence of sugars. Similar MS/MS behavior of this type of saponin in UPLC-qTOF-MS/MS has been reported in the literature (Zhu *et al.*, 2010). To our knowledge, the common hexose and 6-deoxyhexose present in steroidal saponins from Dioscoreaceae are glucose and rhamnose, respectively, and generally, glucosyls are connected with the hydroxyl groups at C-3 and/or C-26 positions of steroidal aglycones.

60

Peak 4 in the total ion chromatogram (TIC) of DP-8 was highlighted by extracted ion chromatogram (EIC). Peak 4 readily produced a strong formate molecular adduct $[M+HCOO]^-$ (m/z 1091.5280) and a weak deprotonated molecular ion $[M-H]^-$ (m/z 1045.4865) in negative mode of ESI-MS. The ion m/z 1091.5280 was further targeted for MS/MS analysis under collision voltages of 40 eV and 60 eV. Figure 6 explains the cleavage path of the sugar chain from the parent ion (m/z 1091.5280), in which m/z differences in the experimental values and calculated values of the glucosyl and rhamnosyl are shown. Results suggest that the unknown compound is a steroidal saponin containing three glucosyls and one rhamnosyl.

Insert Figure 6 here

According to the formula calculator of Agilent MassHunter Workstation Qualitative Analysis software (B.04.00), the most likely elemental composition formula of the unknown compound of peak 4 is $C_{51}H_{82}O_{22}$, the calculated molecular weight of which would be 1046.5298. Referring to the “substances exploration” in the SciFinder[®] Database, based on the retention time and reported structures in the literature (Liu *et al.*, 2007), peak 4 was tentatively identified as pseudoprotogracillin.

For identification of the unknown peak 12 in Figure 3, the mass spectrum of peak 12 (Figure 7) indicates that the fragment ion at m/z 397.3076 was produced by the loss of one water molecule from the protonated molecular ion of diosgenin $[M+H]^+$ (m/z 415.3201). Another fragment ion at m/z 253.1914 could be explained as loss of one neutral fragment $C_8H_{16}O_2$ from the ion at m/z 397.3056 in the positive ion mode of APCI-MS (Zhu *et al.*, 2010). Taking into account the condition of acid hydrolysis, peak 12 was tentatively identified as 3,5-deoxytigogenin, most likely an artifact formed during the hydrolytic cleavage of diosgenin glycosides (Tsukamoto *et al.*, 1957).

Insert Figure 7 here

Quantitative analysis for glycosides and aglycones

Altogether 13 DN samples and 13 DP samples collected from various regions were analyzed by the developed method. From these samples, six glycosides, namely, protodioscin, protogracillin, pseudoprotodioscin, dioscin, gracillin, polyphyllin V, and one aglycone, namely diosgenin, were quantified. The results are shown in Table 3.

Insert Table 3 here

The results show that the highest and the second highest amounts of components were dioscin and protodioscin, respectively, in 10 of 13 batches of DN. For all DP samples, the amounts of protodioscin and protogracillin were in close proportion, ranking either the first or the second highest content in 6 of 13 batches of DP. The content of polyphyllin V was significantly lower than other determined components both in DN and DP samples.

Comparative analyses for chemical composition of DN and DP

Chemical composition of DN and DP was compared in terms of overall chromatographic profile and in terms of quantified constituents. Chromatographic fingerprint similarity was qualitative and quantitative evaluated on the basis of both major and minor peaks detected in chromatograms of DN and DP samples using a Similarity Evaluation Systems for Chromatographic Fingerprint software (Zhejiang University, Version 1.0.1). Test of significance performed by SPSS 16.0 software was used to infer whether the mean contents of individual components could be considered statistically significant between two groups of independent DN and DP samples. Principal component analysis was useful in regression analysis to mitigate the problem of multicollinearity and to explore the relationships among the independent variables (seven determined constituents). This allowed the identification of the primary predictors with minimal multicollinearity, which was accomplished using SIMCA-P 12.0 software.

Evaluation of chromatographic fingerprint similarity

Similarity tests were performed based on the relative retention times and relative peak areas shown in Figure 4 and Figure 5 (Tistaert *et al.*, 2011). The average chromatogram from the 13 batches of DN samples was chosen as the consensus fingerprint. Peak 1 (protodioscin) and peak 5 (dioscin) were selected as the markers by which the peaks and retention times of the other chromatograms were adjusted. In comparison with the consensus fingerprint, all DN samples showed a similarity of at least ≥ 0.95 except the sample DN-13 for which the similarity was 0.89, while a majority of DP samples showed a similarity higher than 0.85, among which 9 samples demonstrated a similarity higher than 0.95, and only the samples of DP-04 and DP-12 showed an exceptionally low similarity of 0.50 and 0.57, respectively (Table 1). Examining the BPC data of samples DP-04 and DP-12 in detail, it was noted that their peak areas of dioscin and gracillin were approximately 1/20 and 1/10 of the corresponding average value of DN, while, moreover, neither of them contained polyphllin V. These anomalies were likely the source of dramatically low similarity with the consensus chromatogram. In general, the two sets of fingerprints revealed a high level of similarity for all main components of DN and DP.

Tests of significance

In addition to comparison of chromatographic profiles of all DN and DP samples, the amounts of seven specific constituents were also compared in both herbs. By independent-samples *t*-test (Table 3), the average content of protodioscin ($P < 0.05$), dioscin ($P < 0.05$) and diosgenin ($P < 0.05$) in DN and DP were significantly different, except protogracillin ($P > 0.05$) and gracillin ($P > 0.05$). The determined values concerning pseudoprotodioscin and polyphyllin V in all samples of DN and DP were subjected to the nonparametric test of two-independent samples due to their inconformity of normality and homogeneity of variance. Results indicated that the average contents of pseudoprotodioscin ($P > 0.05$) in DN and in DP did not differ significantly, while the average contents of polyphyllin V ($P < 0.05$) did differ significantly in these same samples. Overall, the contents of the three major

1
2
3 constituents, namely protogracillin, gracillin and pseudoprotodioscin, were of similar
4 levels while the contents of another three main constituents, namely, protodioscin,
5 dioscin and diosgenin, varied among all samples of DN and DP.
6
7
8
9

10 11 *Principal component analysis*

12
13
14 Principal component analysis (PCA) was employed here to compare DN and DP
15 samples from different sources. Seven determined constituents were set as seven
16 variables, while 26 batches of samples were set as observations. According to factor
17 loading matrix calculations, the PCA loading plot (Figure 8) indicated that
18 protodioscin, dioscin and gracillin showed the greatest influence on Component 1,
19 Component 2 and Component 3, respectively. The three-dimensional graphics of PCA
20 scores (Figure 9) showed that all samples of DN and DP were clustered in their own
21 small regions except DN-13, but they were both within a larger sphere. DN-13, with
22 the lower chromatographic similarity of 0.89, was distributed outside the sphere due
23 to its large score on t3 caused by its very high content of protodioscin. The t1 scores
24 of the DP-04 sample and DP-12 sample (marked by the arrow in Figure 9) with
25 significantly low chromatographic similarity (0.50 and 0.57) were much lower than
26 other samples; this is mainly caused by their dramatically low content of gracillin.
27 The PCA scores of DN samples from different regions did not vary significantly;
28 similarly, the PCA scores of DP samples did not show significant differences. Thus,
29 the PCA results also verified the findings of evaluation of chromatographic fingerprint
30 similarity that DN-13, DP-04 and DP12 varied noticeably c
31 ompared with the rest of samples.

50
51
52
53 Based on the comparative results described above, as for the intra-species
54 difference in chemical composition, it was shown in our present study that the major
55 composition of either DN or DP fluctuated more or less among 13 DN or 13 DP
56
57
58
59
60

1
2
3 samples, respectively. As it is well-known that various factors, such as the
4 environment, growth period, date of collection, stress, the status of being cultivated or
5 collected in the wild might influence the variation of the secondary metabolites
6 accumulate in the body of plants, it is presumed that the big chemical differences for
7 sample DN-13, DP-04 and DP-12 in comparison with the rest of the collections were
8 caused probably due to very complex factors as mentioned above. However, these
9 anomalies only account for the minority of total 26 samples. As for the inter-species
10 similarity in chemical composition between DN and DP, it might be inferred from
11 their classification in phytotaxonomy and their growing environment and ecosystem.
12 The genus of *Dioscorea* is sub-classified into five sections, such as Sect. *Stenophora*
13 Uline, Sect. *Combilium* Prain et Burkill and Sect. *Shannicorea* Prain et Burkill. DN
14 and DP both are classified in Sect. *Stenophora* Uline, which indicates their close
15 genetic relationship. And the growing environment of DN and DP is fairly similar.
16 Both grow in the hillside bush, at the forest edge, or by the roadside on the hill. DN
17 and DP distribute at an altitude of 100-1800 m and 1000-3500 m, respectively
18 (Editorial Board of Flora of China, 1985). Therefore, it is observed that the global
19 similarity in chemical composition is demonstrated both at intra-species and
20 inter-species, and the variations to some extent do exist at intra-species and
21 inter-species.

37
38

39 In conclusion, an efficient and reliable method of UPLC-qTOF-MS was developed
40 for quantitative comparison of six steroidal glycosides and one aglycone of diosgenin
41 in 13 batches of *Dioscorea nipponica* (DN) and 13 batches of *D. panthaica* (DP). The
42 linearity, precision and recovery of this method were fully validated and satisfactorily
43 achieved. Based on the base peak chromatograms acquired and assay results, the
44 chemical profiles of DN and DP were clarified and compared by statistical analyses.
45 Results demonstrate that DN and DP, even from different sources, have a highly
46 similar chemical composition. Thus, it is reasonable to think that, from the aspect of
47 chemical evaluation, DN and DP both can be used as starting material for anti-CHD
48 drugs in the pharmaceutical industry.

Table 3. (continued)

No.	Protodioscin	Protogracillin	Pseudoprotodioscin	Dioscin	Gracillin	Polyphyllin V	Diosgenin
DP-01	11.79 ± 0.08	10.90 ± 0.26	0.36 ± 0.02	7.43 ± 0.08	5.44 ± 0.05	0.36 ± 15.34 × 10 ⁻³	5.63 ± 0.08
DP-02	6.01 ± 0.20	5.07 ± 0.16	5.66 ± 0.14	8.42 ± 0.35	3.87 ± 0.13	0.39 ± 13.96 × 10 ⁻³	4.26 ± 0.15
DP-03	7.43 ± 0.26	4.87 ± 0.14	0.58 ± 0.01	11.26 ± 0.40	6.00 ± 0.29	0.51 ± 5.87 × 10 ⁻³	6.77 ± 0.21
DP-04	4.62 ± 0.15	5.20 ± 0.15	0.81 ± 0.01	0.65 ± 0.02	0.42 ± 0.01	N/A	0.44 ± 0.01
DP-05	13.75 ± 0.66	12.65 ± 0.58	2.75 ± 0.03	5.36 ± 0.25	3.41 ± 0.16	0.30 ± 1.64 × 10 ⁻³	3.32 ± 0.04
DP-06	6.66 ± 0.19	5.49 ± 0.19	22.55 ± 0.53	6.84 ± 0.05	3.68 ± 0.06	0.33 ± 4.68 × 10 ⁻³	4.26 ± 0.26
DP-07	16.09 ± 0.99	13.20 ± 0.79	2.68 ± 0.18	10.15 ± 0.63	5.47 ± 0.29	0.68 ± 5.64 × 10 ⁻³	6.53 ± 0.44
DP-08	7.07 ± 0.54	5.49 ± 0.25	21.15 ± 0.19	6.31 ± 0.19	3.32 ± 0.08	0.27 ± 8.82 × 10 ⁻³	3.29 ± 0.23
DP-09	10.15 ± 0.47	7.80 ± 0.36	2.38 ± 0.12	16.29 ± 0.53	9.08 ± 0.43	0.76 ± 15.52 × 10 ⁻³	13.80 ± 0.93
DP-10	18.46 ± 1.05	19.39 ± 1.09	2.62 ± 0.01	8.29 ± 0.38	6.03 ± 0.41	0.59 ± 15.74 × 10 ⁻³	10.11 ± 0.70
DP-11	17.39 ± 0.44	12.03 ± 0.47	4.41 ± 0.24	9.20 ± 0.32	4.19 ± 0.23	0.42 ± 10.89 × 10 ⁻³	6.89 ± 0.37
DP-12	4.00 ± 0.20	4.44 ± 0.10	5.90 ± 0.28	0.72 ± 0.03	0.52 ± 0.03	N/A	0.45 ± 0.02
DP-13	11.40 ± 0.59	7.72 ± 0.23	12.11 ± 0.37	5.09 ± 0.20	5.17 ± 0.25	0.18 ± 8.06 × 10 ⁻³	3.07 ± 0.20
Average DP	10.37 ± 4.90*	8.79 ± 4.53	6.46 ± 7.50	7.39 ± 4.16*	4.35 ± 2.31	0.37 ± 0.23*	5.29 ± 3.70*

All values are expressed as mean ± standard deviation ($n = 3$);

N/A = Not detected; Average DN and Average DP refer to 13 batches of DN and DP, respectively. * $P < 0.05$

Legends for Figures

Figure 1. Chemical structures of constituents identified in DN and DP.

Figure 2. Typical Base peak chromatogram (BPC) of DN and DP and mixed reference standard solutions for identifying glycosides.

Figure 3. Typical BPC of hydrolyzed samples of DN and DP, and of mixed standard solution of four aglycones.

Figure 4. BPC fingerprint of 13 DN samples.

Figure 5. BPC fingerprint of 13 DP samples.

Figure 6. Elucidation of the unknown compound of Peak 4 by ESI-MS/MS data in negative ion mode.

Figure 7. Mass spectrum of peak 12.

Figure 8. Loading scatter plot of 7 variables on three principal components.

Figure 9. Three-dimensional graphics of PCA scores of 13 batches of DN and DP respectively.

Type of chemical structure	Chemical name	Molecular formula	R ₁
	Diosgenin	C ₃₉ H ₄₂ O ₃	- H
	Dioscin	C ₄₅ H ₇₂ O ₁₆	- β - D - Glc(4←1) - α - L - Rha (2←1)
Spirostanol sapogenin /saponins	Gracillin	C ₄₅ H ₇₂ O ₁₇	α - L - Rha - β - D - Glc(3←1) - β - D - Glc (2←1)
	Polyphyllin V	C ₃₉ H ₆₂ O ₁₂	α - L - Rha - β - D - Glc(2←1) - α - L - Rha
			R ₂
Furosta-5-en-type saponins	Protodioscin	C ₅₁ H ₈₄ O ₂₂	- β - D - Glc(4←1) - α - L - Rha (2←1)
			α - L - Rha
			R ₃
Furosta-5,20 (22)-dien-type saponins	Pseudoprotodioscin	C ₅₁ H ₈₂ O ₂₁	- β - D - Glc(4←1) - α - L - Rha (2←1)
			α - L - Rha
	Pseudoprotogracillin	C ₅₁ H ₈₂ O ₂₂	- β - D - Glc(2←1) - α - L - Rha (3←1)
			β - D - Glc

Figure 1. Chemical structures of constituents identified in DN and DP.

Figure 2. Typical Base peak chromatogram (BPC) of DN, DP and mixed reference standard solutions for identifying glycosides. (1. Protodioscin, 2. Protogracillin, 3. Pseudoprotodioscin, 4. Pseudoprotogracillin, 5. Dioscin, 6. Gracillin, 7. Polyphyllin V)

Figure 3. Typical BPC of hydrolyzed samples of DN and DP, and of mixed standard solution of four aglycones (9. Ruscogenin, 10. Diosgenin, 11. Tigogenin and sarsasapogenin, 12. 3,5-deoxytigogenin).
