22

23 **Abstract:**

24 Ethanol precipitation is one of the most widely used methods for preparing natural  
25 polysaccharides, in which ethanol concentration significantly affects the precipitate  
26 yield, however, is usually set at 70-80%. Whether the standardization of ethanol  
27 concentration is appropriate has not been investigated. In the present study, the  
28 precipitation yields produced in varied ethanol concentrations (10-90%) were  
29 qualitatively and quantitatively evaluated by HPGPC (high-performance  
30 gel-permeation chromatography), using two series of standard glucans, namely  
31 dextrans and pullulans, as reference samples. The results indicated that the response  
32 of a polysaccharide's chemical structure, with diversity in structural features and  
33 molecular sizes, to ethanol concentration is the decisive factor in precipitation of these  
34 glucans. Polysaccharides with different structural features, even though they have  
35 similar molecular weights, exhibit significantly different precipitation behaviors. For a  
36 specific glucan, the lower its molecular size, the higher the ethanol concentration  
37 needed for complete precipitation. The precipitate yield varied from 10% to 100% in  
38 80% ethanol as the molecular size increases from 1 kDa to 270 kDa. Our trials, using  
39 different ethanol concentrations to extract the polysaccharides from water extracts of  
40 eight natural materials, demonstrate and confirm that natural polysaccharides respond  
41 differently to different concentrations of ethanol in ethanol precipitation extractions.  
42 This paper aims to draw scientists' attention to the fact that, in extracting natural  
43 polysaccharides by ethanol precipitation, the ethanol concentration must be  
44 individually optimized for each type of material.

45

47 structures; Ethanol concentration

48

49 **1. Introduction**

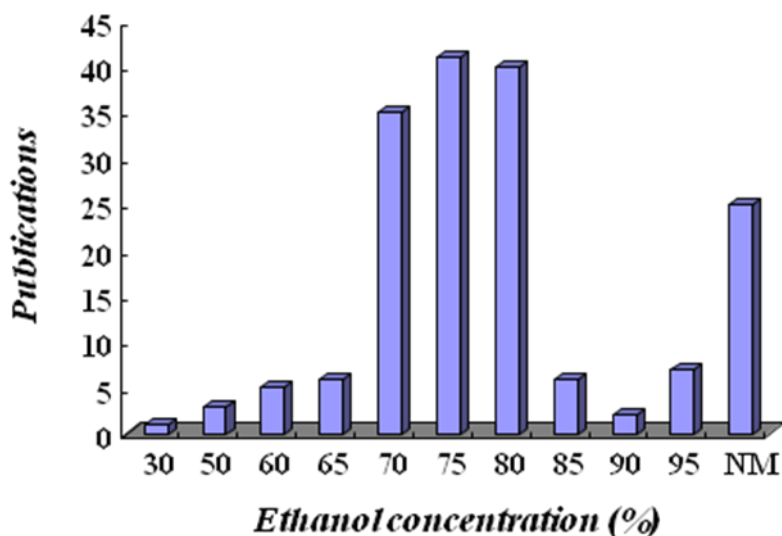

50 Natural polysaccharides are important biologically active components of many  
51 medicinal herbs, and have thus been attracting increasing multidisciplinary research  
52 interest [1]. Several challenges exist in this research field: crystal structure  
53 determination, quality control, *in vivo* detection, and molecular target determination  
54 [2-5]. However, before these challenges can be effectively tackled, a more  
55 fundamental problem must be addressed, namely, accurate, consistent sample  
56 preparation [6-8].

57

58 As the commonly-used sample pretreatment operation, ethanol precipitation is  
59 generally the first step in preparing crude polysaccharides from water extracts [9-11].  
60 To some extent, the methodology of ethanol precipitation for some specific samples,  
61 e.g. *Citrus* pectins [12], inulinases [13], water extracts of Danshen (*Salvia miltiorrhiza*  
62 Bge.) and Chuanxiong (*Ligusticum chuanxiong* Hort.) [14], was investigated in terms  
63 of ethanol concentration, supernatant pH value, and refrigeration temperature. The  
64 results indicated that the yield of total saccharides increases as ethanol concentration  
65 increases. The effect of supernatant pH value is not very significant. Although  
66 temperature decrease from 25-5 °C also leads to an increase of saccharide yield, as  
67 the precipitation is usually performed at around 4 °C in a laboratory refrigerator,  
68 ethanol concentration seems to be the most important variable in ethanol precipitation.

69 We found and reviewed a total of 171 publications in *ScienceDirect* from Jan 1 to  
70 May 30, 2013 (Figure 1) in which ethanol precipitation was used for the preparation  
71 of natural polysaccharide. In more than 70% of these publications—i.e., an

72 overwhelming majority--the ethanol concentration used was 70-80%, which seems a  
73 standardized condition. Approximately 15% of these papers did not mention the  
74 ethanol concentration they used, suggesting that ethanol concentration was not  
75 considered important. And none of these publications include an optimization of the  
76 ethanol concentration. Some questions naturally arise: Will a fixed ethanol  
77 concentration (e.g., 70-80%) completely precipitate all polysaccharides in every type  
78 of natural product? Will varied ethanol concentrations extract different  
79 polysaccharides from the same sample? Will different polysaccharides within similar  
80 molecular sizes share the same optimal ethanol concentration? Should ethanol  
81 concentration be optimized for each natural product?

82

83 Fig. 1 The statistical results of the ethanol concentration used for polysaccharide  
84 precipitation from natural products in the published paper in *Science Direct* Database  
85 since Jan, 2013 (data was processed on May 30, 2013) (NM: not mentioned)

86

87 In order to answer these questions, in the current study we first used two series of  
88 reference glucans, branched dextrans and unbranched pullulans, to qualitatively and  
89 quantitatively evaluate the effect of ethanol concentration on the precipitation of  
90 polysaccharide by HPGPC (high performance gel permeation chromatography).  
91 Multiple parameters that could affect the ethanol precipitation results, such as  
92 structural features, molecular size, and ethanol concentration, were systematically  
93 investigated. Eight commonly-used polysaccharide-rich herbal/fungi materials were  
94 then used as natural samples to determine if and how variation in ethanol  
95 concentration affected polysaccharide precipitation.

96

## 97 **2. Experimental**

### 98 **2.1 Materials and chemicals**

99 Eight commonly used medicinal herbs/fungi, namely *Angelica sinensis*,  
100 *Codonopsis pilosula*, *Dendrobium officinale*, *Ligusticum wallichii*, *Panax ginseng*,  
101 *Panax notoginseng*, *Ganoderma lucidum* and *Ganoderma sinensis*, were selected as  
102 representative polysaccharide-rich natural samples. The herbal/fungi materials were  
103 purchased from herb markets in mainland China and were authenticated by Dr. Chen  
104 Hubiao. The voucher specimens were deposited at School of Chinese Medicine, Hong  
105 Kong Baptist University, Hong Kong, China.

106

107 Deionized water was prepared by Millipore Milli Q-Plus system (Millipore,  
108 Bedford, MA, USA) and ethanol was purchased from RCI Labscan Ltd. (Bangkok,

109 Thailand). The reference glucan substances, dextrans and pullulans (Figure 2) with  
110 known molecular sizes (1-270 kDa for dextrans, 6-805 kDa for pullulans), and  
111 glucose were bought from Sigma (St. Louis, MO, USA).

113 Fig. 2 Chemical structures of reference polysaccharides, branched dextrans (A) and  
114 unbranched pullulans (B).

115

## 116 2.2 Preparation of water extracts

117 Herbal material was dried and powdered. For each sample, 10 g of powder was  
118 first ultrasonically extracted with 100 mL of acetone for 1 h to remove liposoluble  
119 substances, and then reflux-extracted with water at 100 °C (100 mL) for one hour,  
120 twice. The decoctions were combined and centrifuged at 3500 rpm for 10 min. The  
121 total sugar content in the solution, calculated as glucose, was adjusted to about 2.0  
122 mg/mL for further analysis [15].

123

## 124 2.3 Ethanol precipitation

125 Aqueous stock solutions of dextrans and pullulans with different molecular  
126 weights (2 mg/mL, 5 mL) were precipitated by adding ethanol to make a final  
127 concentration of 10-90% (v/v), respectively, and left overnight (12 h) at 4 °C. After

128 centrifugation (3500 rpm) for 10 min, the precipitate was collected, washed with  
129 ethanol, dried (water bath, 70 °C) to remove any residual ethanol, and then was  
130 completely re-dissolved in 5 mL hot water (60 °C) by drastic mechanical vibration for  
131 2 hours. Finally, each solution was filtered through a 0.22 µm syringe filter (Agilent  
132 Technologies, USA) for HPGPC analysis [16]. Solutions of the herbal samples were  
133 prepared using the same method.

134

#### 135 **2.4 HPGPC analysis**

136 HPGPC analyses were performed on an Agilent 1100 series (Agilent  
137 Technologies, Palo Alto, CA) equipped with DAD and ELSD and two tandem TSK  
138 GMPW<sub>XL</sub> columns (300 mm×7.8 mm i.d., 10 µm) at 40 °C. Ammonium acetate  
139 aqueous solution (20 mM) was used as mobile phase at a flow rate of 0.6 mL/min.  
140 DAD was set at 260nm and 280 nm. The parameters of ELSD were set as: the drift  
141 tube temperature was 120 °C, and nebulizer nitrogen gas flow rate was at 3.2 L/min,  
142 impact-off mode. An aliquot of 20 µL solution was injected for analysis. Because  
143 polysaccharides have no UV absorption, UV detector was set at 260 nm and 280 nm  
144 in order to monitor the existence of nucleic acid and/or peptide in this study.

145

146 Aqueous stock solutions of dextrans and pullulans with different molecular  
147 weights were diluted to appropriate concentrations for the construction of calibration  
148 curves. At least five concentrations of each solution were analyzed in duplicate, and

149 then the calibration curves were constructed by plotting the logarithm of the peak area  
150 versus concentration of each analyte.

151

### 152 **3. Results and discussion**

#### 153 **3.1 Impact of ethanol concentration, molecular size and structural features**

154 The reference standards dextrans and pullulans were precipitated at different  
155 concentrations of ethanol (10-90%). The obtained precipitates were quantitatively  
156 determined using the established HPGPC calibration curves (Table 1). The recovered  
157 yields of these glucans are shown in Figure 3, and their individual HPGPC  
158 chromatogram can be found in Supplementary Figures 1 and 2.

159

160 **Table 1** Calibration curves of the HPGPC quantitative assay of dextrans and  
 161 pullulans.

	<b>Mw (kDa)</b>	<b>Range (mg/mL)</b>	<b>Equation</b>	<b>R<sup>2</sup></b>
<i>Dextrans</i>	1	0.13~4.23	$y=1.8387x+3.8191$ <sup>a</sup>	0.9981

163

164

165 Fig. 3 Effects of ethanol concentration (10-90%) on the precipitation of dextrans (A)

166 and pullulans (B) from aqueous solution (n=3)

167

168 As demonstrated in Figure 3, both series of glucan standards exhibit a consistent

169 trend in that the precipitate yield steadily increases as ethanol concentration increases,

170 as investigated, from 10% to 90%. This is consistent with the findings in the

171 published report [14].

172 More importantly, results suggest that molecular size affects yield: those with  
173 larger molecular size could be easily precipitated at a lower ethanol concentration  
174 (Figure 3). For example, when ethanol concentration is set at 50%, the precipitate  
175 yield reaches 90% for 270 kDa of dextran, while it decreases to zero for 1 kDa. At the  
176 most commonly used ethanol concentration of 80%, precipitate yield from dextrans  
177 increased from 10% to 100% as molecular size increased from 1 kDa to 270 kDa.  
178 Among them, dextrans of both 5.0 kDa and 1.2 kDa generated close yields around  
179 60%. In other words, not all polysaccharides could be completely precipitated in 80%  
180 ethanol.

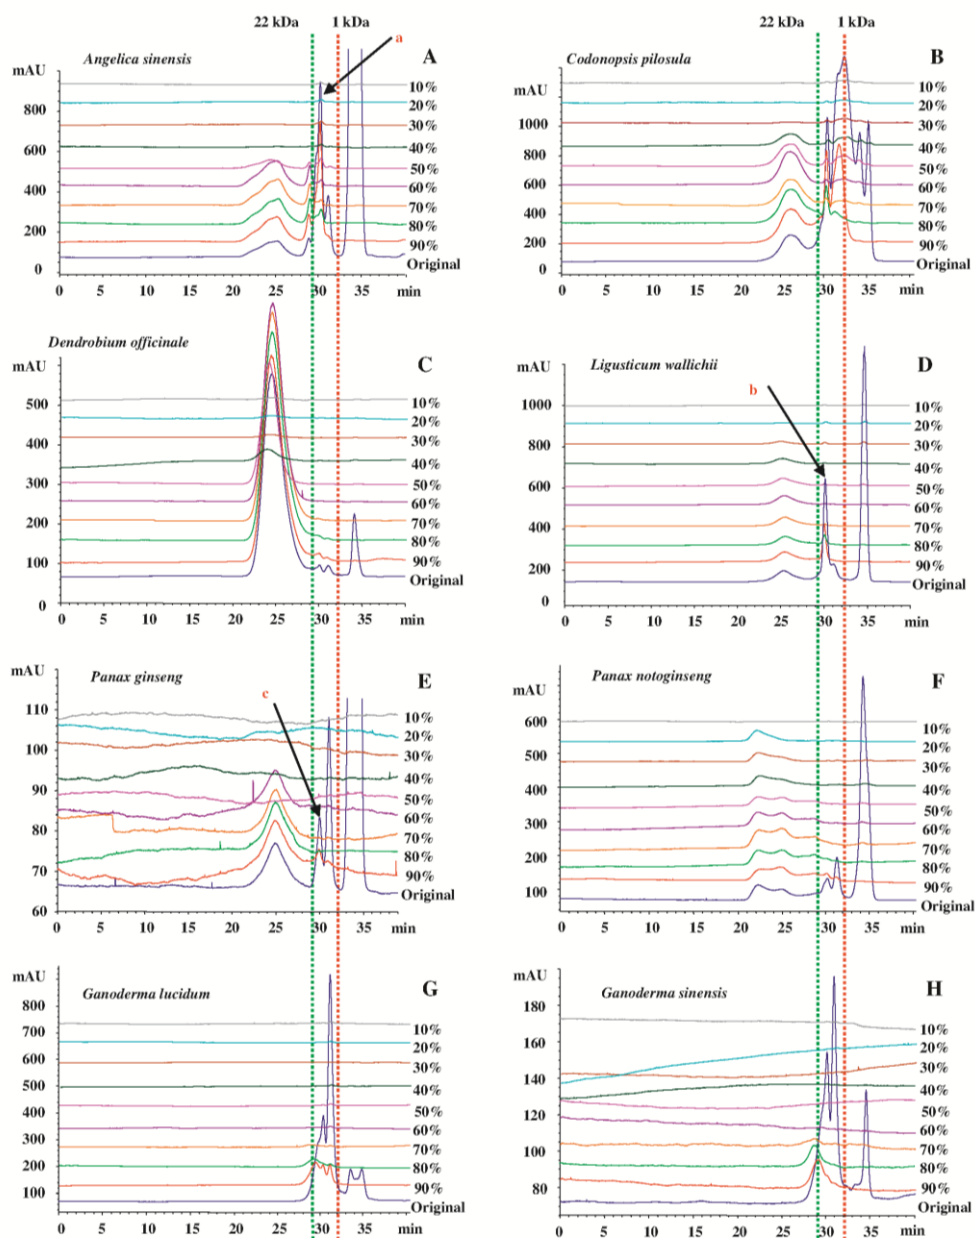

181 Another factor apparently affecting precipitate yield is the physical structure of  
182 polysaccharides. Of these two kinds of reference polysaccharides, which have the  
183 same sugar composition and similar molecular size, one is branched and the other is  
184 unbranched (Figure 2), and they exhibited distinctively different ethanol precipitation  
185 behaviors. Pullulan, the branched glucan, seems to be precipitated more easily. As  
186 demonstrated in Figure 3, in 70% ethanol, pullulan with a molecular size of 48.8 kDa  
187 was completely precipitated, while dextran with a similar molecular size of 50 kDa  
188 was only 70% extracted. Moreover, in 90% ethanol, pullulan of 6 kDa was fully  
189 precipitated, while dextran of 5 kDa was only 50% extracted. If we want to ensure a  
190 high yield above 90%, the minimum ethanol concentration needs to be set at 50% for  
191 pullulan with molecular sizes of 48.8 kDa and above, while for dextran with similar  
192 molecular size, it needs to be 80%.

193 In summary, our results indicate that molecular size and structure influence  
194 polysaccharide precipitation in ethanol. Different concentrations of ethanol precipitate  
195 different polysaccharides to greater and lesser extents. Thus, for maximum yield of  
196 any given polysaccharide, the ethanol concentration must be individually optimized.

197

### 198 **3.2 Further tests on natural samples**

199 Our tentative conclusion was confirmed in further tests on natural materials that  
200 are rich in polysaccharides. First, high diversity in the molecule distribution pattern of  
201 these investigated natural materials was revealed by HPGPC-ELSD-UV analysis. As  
202 shown in Figure 4 (the originals), small molecules below 1 kDa are dominant in  
203 *Angelica sinensis* and *Panax ginseng*; molecules in the range of 1-22 kDa are in the  
204 majority in both *Ganoderma* species, yet in the minority in *Dendrobium officinale*;  
205 macromolecules beyond 22 kDa were dominant in *Dendrobium officinale*, but hardly  
206 found in *Ganoderma* samples. Any influence from nucleic acids or peptides was  
207 excluded because the major ELSD peaks had no obvious UV absorbance under the  
208 investigated conditions (data not shown).

209

210 Fig. 4 HPGPC chromatograms of water extracts of investigated herbal materials  
 211 before (original) and after (10-90%) ethanol precipitation. A. *Angelica sinensis*, B.  
 212 *Codonopsis pilosula*, C. *Dendrobium officinale*, D. *Ligusticum wallichii*, E. *Panax*  
 213 *ginseng*, F. *Panax notoginseng*, G. *Ganoderma lucidum* and H. *Ganoderma sinensis*

214

215 These natural polysaccharides responded significantly differently to variations in  
 216 ethanol concentration. For instance, as shown in Figure 4A, peak a in *Angelica*

217 *sinensis* was mostly released into its 90% ethanol precipitate; while for peak b in  
218 *Ligusticum wallichii* and peak c in *Panax ginseng*, both possessing molecular size  
219 similar to peak a (based on the identical retention time), only around half of them  
220 were obtained after 90% ethanol precipitation (Figure 4D and 4E). More significantly,  
221 the critical ethanol concentration for macromolecules beyond 22 kDa varied greatly in  
222 different cases: it was 60% for *Angelica sinensis* (Figure 4A) and *Panax ginseng*  
223 (Figure 4E), 40% for *Codonopsis pilosula* (Figure 4B), 50% for *Dendrobium*  
224 *officinale* (Figure 4C), 30% for *Ligusticum wallichii* (Figure 4D), and 20% for *Panax*  
225 *notoginseng* (Figure 4F).

226

### 227 **3.3 Impact of other factors**

228 In this study, other factors like precipitation (a) time, (b) temperature, and the (c)  
229 original sample concentration were also evaluated for their impact on ethanol  
230 precipitation of polysaccharides. The results indicated that they are not decisive  
231 factors. (a) It was found that the solubility of polysaccharides in ethanol is so poor  
232 that the precipitation of polysaccharides is always quickly finished within minutes.  
233 Hence, time is not a factor. (b) Polysaccharides exhibit relatively stable solubility  
234 between 4°C and room temperature (25°C). And the precipitation is usually performed  
235 at around 4 °C in a laboratory refrigerator. Hence, temperature in the average  
236 laboratory is not a factor. (c) As for the original sample concentration, no significant  
237 variation in the precipitate yield was observed during a wide range of concentrations  
238 (2-40 mg/ml, Supplementary Figure 3). While, theoretically, too little precipitate for

239 detection might be produced if the concentration is too low, in practice this is seldom  
240 a cause for concern.

241

#### 242 **4. Concluding remarks**

243 In conclusion, our work demonstrates that chemical diversity in polysaccharides  
244 including different structural features and varied molecular sizes is the decisive factor  
245 of ethanol precipitation of polysaccharides. Polysaccharides with different structural  
246 features and molecular sizes will precipitate to different degrees in different  
247 concentrations of ethanol. This has significant implications for researchers.  
248 Currently, an overwhelming majority of researchers use 70-80% ethanol for  
249 precipitation. This might be appropriate for comparison work, however, in cases  
250 where the goal is different, e.g. to extract as much or as many polysaccharides as  
251 possible from a given sample, it is strongly recommended that the ethanol  
252 concentration used in precipitation of natural polysaccharides should be individually  
253 optimized in advance.
